

**LOW RELATIVE INTENSITY NOISE
FIBER GRATING TYPE LASER DIODE**

ABSTRACT OF THE DISCLOSURE

5 The dependency of intensity noise is used to determine the wavelength
difference between a laser diode gain peak and a reflection peak of a fiber
grating in a fiber grating type laser diode. Monitoring and determining the
relative noise intensity of such a laser enables the control of the laser diode or
the fiber grating such that the intensity noise is as low as possible. Such an
10 approach enables the use of a fiber grating type laser diode as Raman pumps
in high-speed transmission systems where low intensity noise is a requirement,
especially when the Raman pump power propagates in the same direction as
the transmission signals (known as Raman co-pumps)..
